Primary Hypothesis

 Catheter ablation-based AF rhythm control as compared with rate control reduces the primary outcome of all-cause mortality and HF events in patients with AF and HF of either LVEF ≤45% or LVEF >45%

Secondary Hypotheses

- Catheter ablation-based AF rhythm control as compared with rate control reduces the primary outcome of all-cause mortality and HF events in patients with AF and HF of LVEF ≤45%
- Catheter ablation-based AF rhythm control as compared with rate control reduces the primary outcome of all-cause mortality and HF events in patients with AF and HF of LVEF >45%

Study Design

- Parallel, randomized controlled trial
 - Eligible patients were randomly assigned in a 1:1 ratio to receive
 - Ablation-based rhythm control
 - Rate control
 - Stratified by center, LVEF (≤45%, >45%), and atrial fibrillation type
- 21 centres from Canada, Sweden, Brazil and Taiwan
- PROBE (Prospective Randomized Open Blinded End-point) design
- Trial Interventions:
 - Ablation-based rhythm control one or more ablations for AF with Pulmonary Vein Isolation ±
 addition lesions; antiarrhythmic drug used for AF recurrence after more than one ablation
 procedures
 - Rate control AV nodal blockers ± ablate and bi-V pace targeting a resting HR ≤80 bpm and post 6-minute walk HR ≤110 bpm

- Patients with one of the following AF type (at least one ECG of AF)
 - 1. High Burden Paroxysmal AF: ≥4 episodes of AF in the last 6 months, and at least one episode >6 hours (not required cardioversion) and was <7 days
 - 2. Persistent AF 1: AF episodes <7 days but requires cardioversion
 - 3. Persistent AF 2: at least one episode of AF >7 days but not >1 year
 - 4. Long-term Persistent AF: at least one episode >one year, but not <3 years
- Optimal therapy for heart failure of at least 6 weeks
- Heart failure with NYHA class II or III symptoms
- Either impaired LV function (LVEF ≤45%) or preserved LV function (LVEF >45%) determined within 12 months prior to enrollment
- Suitable candidate for catheter ablation or rate control for the treatment of AF
- Age ≥18
- NT-proBNP/BNP

Current rhythm	HF hospitalization in last 9 months	NT pro-BNP
AF	Yes	≥ 600 pg/mL
AF	No	≥ 900 pg/mL
Sinus	Yes	≥ 400 pg/mL
Sinus	No	≥ 600 pg/mL

Primary and Secondary Outcome Measures

- Primary Outcome: Composite of time to death or HF event
 - HF event was defined as an admission to a healthcare facility for >24 hours OR clinically significant worsening HF leading to administration of an intravenous diuretic, and an increase in chronic HF therapy in an emergency department or unscheduled visit to a healthcare provider
- Secondary Outcomes: death, HF event, change in LVEF, NT-proBNP, six-minute walk distance, and quality of life at 12 and 24 months
- The primary and secondary outcomes were evaluated in patients with LVEF ≤45% and >45%.
- Subgroup analysis (not stratified): sex, diabetes, hypertension, underlying heart disease, NYHA class

Trial Progress

- Initial sample size was calculated to be 600 (300 per study group)
 - 30% relative risk reduction of the primary outcome
 - Annual event rate 17% in the rate control group, 11.9% in the rhythm control group
 - Loss of follow-up = 2%; crossover = 2%
- In January 2018, recruitment was stopped on the recommendation of the Data Monitoring Committee after the interim analysis due to
 - Lower than expected enrollment rate
 - Lower than expected event rate
 - Perceived futility, based on the data of 363 patients followed for a median of 19.5 months — Futility index of 0.81

at 24 months	39.2±11.7	77.1±9.2	31.3 (22.1, 31.2)	~ 0.0001
Change in LVEF from baseline at 12 months(%)	4.1±1.0	7.7 ± 0.9	3.2 (0.6, 5.9)	0.017
at 24 months	3.8±1.2	10.1±1.2	3.2 (0.0, 3.9)	0.017

^a Treatment Effect is reported as HR (Hazard Ratio) with 95% CI (Confidence Interval)

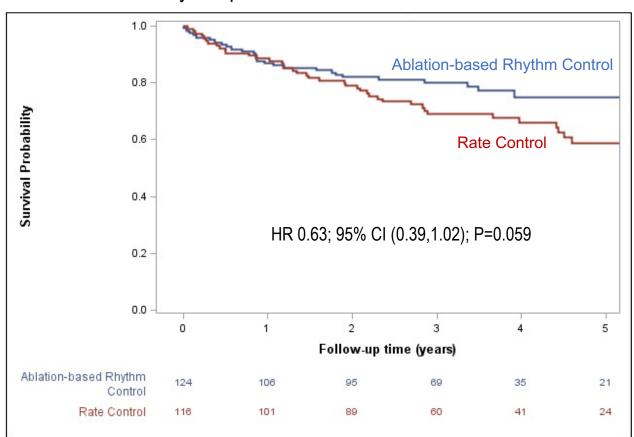

^b Effect Size with 95% CI determined using the joint model accounting for the competing risk of death

c Changes of Quality-of-Life score, 6-minute walk distance, NT-proBNP and LV ejection fraction at 12, 24 months from baseline are expressed as the least square mean difference (LSMD)±standard error (SE) using a repeated measures linear mixed effects model including group, visit, and group×visit interaction.

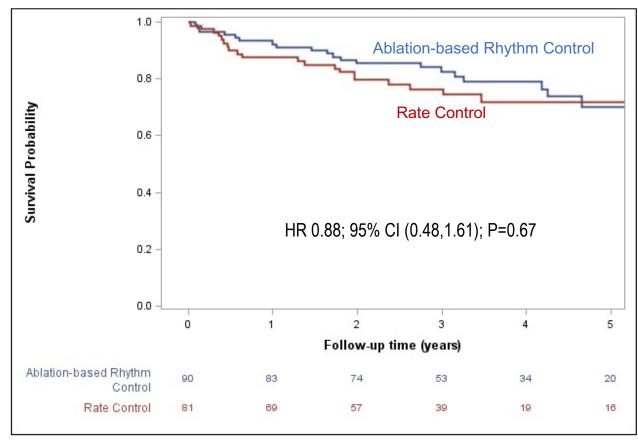

All-cause Mortality and HF Events by LVEF

Primary Endpoint in Patient with LVEF ≤45%

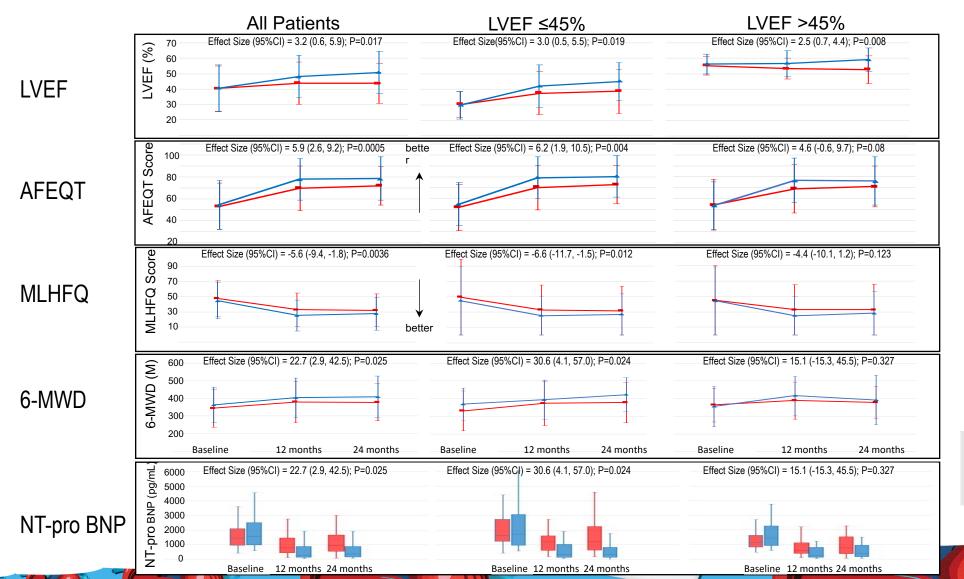

Primary Endpoint in Patient with LVEF >45%

Supportive Secondary Outcomes

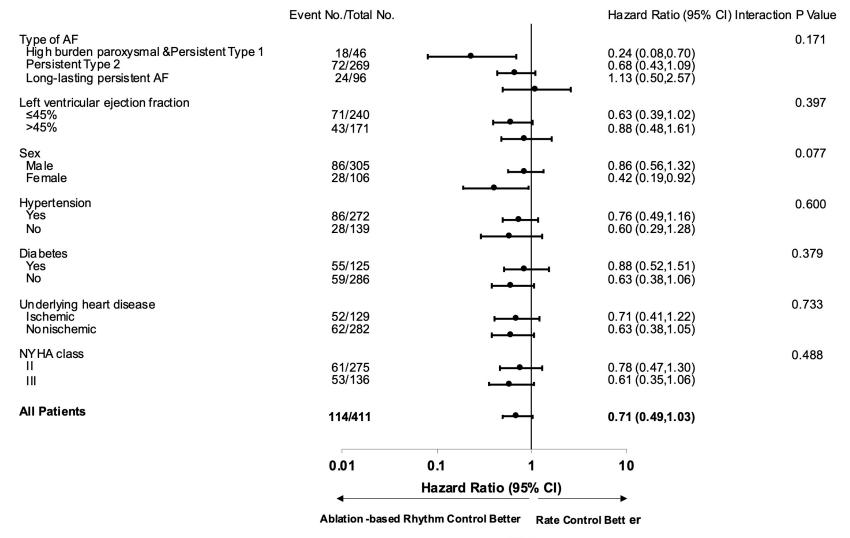

Rate control

Ablation-based rhythm control

Effect size is an estimate of the difference between groups taking into account of time and competing risk of death

Conclusions

- In this trial of patients with AF and HF, the reduction of all-cause mortality and HF events with ablation-based rhythm control did not reach statistical significance as compared to rate control.
- Patients in the ablation-based rhythm control group had numerically fewer primary outcome events, and greater improvement of LV function, improvement of quality of life and reduction of NT-pro BNP than patients in the rate-control group.
- There was no difference in the number of patients with serious adverse events in the two study groups.
